Cop. 2

FRESH PRODUCE STORAGE

PRC 1 A STATE OF A FILE

This correspondence aid presents brief summaries in Tables 1 and 2 of the average storage requirements of fresh fruits and vegetables. The conditions given should not be considered absolute or final but rather as the safe limitations under which the various products can ordinarily be stored.

The temperatures recommended are the optimum for long storage. For short storage, higher temperatures may be satisfactory for some commodities. Conversely, products susceptible to chilling injury can sometimes be held at a temperature lower than indicated for several days without injury. Exceptions include bananas, cucumbers, eggplant, okra, pumpkins and squashes, sweetpotatoes, and mature green tomatoes. Recommended temperatures for these products should be strictly adhered to. Susceptibility to chilling is discussed in greater detail in the section on chilling injury.

Recommendations for the best conditions for storage of fresh fruits and vegetables may change from time to time as varieties and handling methods change and as more information is gained on storage requirements of these commodities.

Temperature

Refrigerated storage is recommended for many perishable commodities because it retards: (1) respiration and other metabolic softening, and textural and color changes; (3) moisture loss and the resultant wilting; (4) spoilage caused by invasion by bacteria, fungi, and yeasts; and (5) undesirable growth, such as sprouting of potatoes. All temperature recommendations are given in degrees Fahrenheit.

activity; (2) aging caused by ripening,

If the best results are to be obtained in cold storage, the temperature in storage rooms must be held fairly constant. Variations of 2° or 3° F. above or below the desired temperature are too large in most cases. For example, most varieties of apples keep best and longest if held constantly at 30° to 32°; the best temperature for pears is between 29° and 30°. If the air temperature where either of these fruits is stored rises 2° or 3° above the upper limit mentioned or if the commodity is not cooled promptly to these temperatures, there is danger of increased decay and undue ripening. The danger is greater the longer the period during which the temperature is above the optimum.

For example, 3 or 4 days at 35° usually would have little or no effect, partly because of a slower rise in the temperature of the fruit than in that of the air; but 10 days at this temperature would probably shorten the life of the fruit by about a week and possibly result in more decay. On the other hand, if the temperature goes 1° or 2° below 29°, in a pear storage there is a chance that freezing will occur.

Celery and cabbage allowed to remain too warm in storage will show yellowing and decay; potatoes are likely to begin to sprout if the temperature is too high and to become

¹Information supplied by Robert E. Hardenburg, Northeastern Region.

undesirably sweet if it is too low. Other commodities undergo these or other kinds of deterioration if the temperature variations throughout long storage periods exceed the limits given for them in the tables. In addition, fluctuations in temperature often cause condensation of moisture on stored products, which is undesirable because it may favor the growth of mold and the development of decay.

Maintaining uniform temperatures in all parts of a storage room is more important than avoiding small fluctuations at a given point. Fruit stored in a part of the room where the temperature is continuously higher than in another part ripens faster than that stored in the cooler part. This frequently results in mixing of overripe and prime fruit on removal, or it may result in undetected deterioration and decay in inaccessible locations.

Temperature variations can usually be prevented if the storage rooms are well insulated throughout and have adequate refrigeration and if the spread between the temperature of the refrigerant and that of the room to be refrigerated is kept small. Proper stacking and adequate air circulation also help to minimize temperature variation. Storage rooms should be equipped either with reliable, accurate thermostats or with manual controls that are given frequent personal attention by someone charged with that duty. Even when reliable automatic controls are used, they should be checked periodically.

In commercial cold-storage rooms, thermometers are usually placed at a height of about 5 feet for convenience in reading. It is important, however, to take temperatures frequently at the floor and the ceiling levels and at any other places where they might be expected to be undesirably high or low. It would be short-sighted to rely on just one or two aisle temperatures.

Product temperatures should be taken in packages or within bulk containers at various locations. A thermometer of good quality is essential; accurate temperatures cannot be expected from a poor one. Either a glass stem thermometer or a metal dial thermometer is recommended for taking temperatures of fresh produce. These should be checked occasionally to insure their accuracy. The test can be made by immersing a thermometer in and iceand-water bath. Fill a pint-size container with

chipped ice and then add water. Stir for 2 minutes and then immerse the thermometer for 2 minutes in the center of the mixture. Do no permit the thermometer bulb to rest against the side or bottom of the container. The thermometer should read with 1° , plus or minus, of 32° F.

Temperatures in less accessible locations, such as the middle of stacks, can be obtained conveniently with distant-reading thermometer equipment, such as thermocouples or electrical resistance thermometers.

Relative Humidity

The relative humidity of the air in storage rooms directly affects the keeping quality of produce. If it is too low, wilting or shriveling is likely to occur; if it is too high, it may favor the development of decay. Maintaining relative humidity high enough is usually a much greater problem than too high humidity in storages. High relative humidities of 90 to 95 percent are recommended for most perishable horticultural products, to retard softening and wilting from moisture loss. A few exceptions are shown in the tables.

Of major importance in maintaining adequate relative humidity in the storage air is providing good insulation, avoiding leaks, and providing sufficient cooling surface so that the spread between the temperature of the refrigerating surface and the desired commodity temperature is as small as possible, often only 1° to 2° F. Relative humidity may be checked with a sling or fan-operated psychrometer or with various types of hygrometers.

Chilling Injury

Certain fruits and vegetables are injured by low (32° to 50° F.) but nonfreezing temperatures. At these temperatures they become weakened because they are unable to carry on normal metabolic processes. Often products that are chilled look sound when removed from low temperatures, however, symptoms of chilling, such as pitting or other skin blemishes, internal discoloration, or failure to ripen, become evident in a few days at warmer temperatures. Susceptible fruits and vege-

tables that have been chilled may be particularly susceptible to decay. Alternaria rot is often severe on tomatoes, squash, peppers, and cantaloups that have been chilled.

Both time and temperature are involved in chilling injury. Damage may occur in a short time if temperatures are considerably below the danger line, but a product may be able to withstand a few degrees in the danger zone for a longer time. However, with some products such as grapefruit and cucumbers, injury may become apparent sooner at temperatures only slightly below the optimum than at lower temperatures. The effects of chilling are cumulative. Low temperatures in transit, or even in the field shortly before harvest, add to the total effects of chilling that might occur in storage.

Freezing Injury

The temperature usually recommended for storing fresh commodities are shown in tables

1 and 2. The highest temperatures at which freezing may occur also is shown. Always avoid subjecting fresh produce to freezing temperatures. Tissues injured by freezing generally appear water soaked and may be especially subject to decay.

Different commodities vary widely in their susceptibility to freezing injury. Some may be frozen and thawed a number of times with little or no injury while others are permanently injured by even slight freezing. The freezing point of the commodity is no indication of the damage to be expected by freezing or chilling.

For example, tomatoes and parsnips both have freezing points of 30° to 31° F., but parsnips can be frozen and thawed several times without apparent injury while tomatoes are ruined after one freezing. As with chilling injury, severity of freezing injury is influenced by a combination of time and temperature. Apples that would be injured little by exposure for a few days at temperatures slightly below the freezing point would be severaly injured by just a few hours' exposure to 15° to 20° F.

Table 1.—Recommended temperature and relative humidity, approximate storage life, and highest freezing point of fresh fruits in commercial storage

| Commodity | Storage tempera- ture | Relative humidity | Approximate length of storage period | Highes freezin point |
|--|-----------------------------|----------------------|--|----------------------------|
| | °F. | Percent | | $^{\circ}F.$ |
| Apples ¹ | 30 to 40 | 90 | 3 to 8 months | 29.3 |
| Apricots | 31 to 32 | 90 | 1 to 2 weeks | 30.1 |
| Avocados ¹ | 40 to 55 | 85 to 90 | 2 to 4 weeks | 31.5 |
| Bananas | 56 to 58 | 90 to 95 | Variable | 30.6 |
| Berries | | | | |
| Blackberries | 31 to 32 | 90 to 95 | 2 to 3 days | 30.5 |
| Blueberries | 31 to 32 | 90 to 95 | 2 weeks | 29.7 |
| Cranberries | 36 to 40 | 90 to 95 | 2 to 4 months | 30.4 |
| Currants | 31 to 32 | 90 to 95 | 1 to 2 weeks | 30.2 |
| Dewberries | 31 to 32 | 90 to 95 | 2 to 3 days | 29.7 |
| Elderberries | 31 to 32 | 90 to 95 | 1 to 2 weeks | |
| Gooseberries | 31 to 32 | 90 to 95 | 2 to 4 weeks | 30.0 |
| Loganberries | 31 to 32 | 90 to 95 | 2 to 3 days | 29.7 |
| Raspberries | 31 to 32 | 90 to 95 | 2 to 3 days | 30.0 |
| Strawberries | 32 | 90 to 95 | 5 to 7 days | 30.6 |
| Cherries, sour | 32 | 90 to 95 | 3 to 7 days | 39.0 |
| Cherries, sweet | 30 to 31 | 90 to 95 | 2 to 3 weeks | 28.8 |
| Coconuts | 32 to 35 | 80 to 85 | 1 to 2 months | 30.4 |
| Dates | 0 to 32 | 75 | 6 to 12 months | 3.7 |
| Figs, freshGrapefruit, | 31 to 32 | 85 to 90 | 7 to 10 days | 27.6 |
| California and Arizona Grapefruit, | 58 to 60 | 85 to 90 | 4 to 6 weeks | |
| Florida and Texas | 50 | 85 to 90 | 4 to 6 weeks | 30.0 |
| Grapes, Vinifera | 30 to 31 | 90 to 95 | 3 to 6 months | 28.1 |
| Grapes, American | 31 to 32 | 85 | 2 to 8 weeks | 29.7 |
| Guavas | 45 to 50 | 90 | 2 to 3 weeks | |
| Lemons | 38 to 55 | 85 to 90 | 1 to 4 months | 29.4 |
| Limes | 48 to 50 | 85 to 90 | 6 to 8 weeks | 29.1 |
| Lychees | 35 | 90 to 95 | 3 to 5 weeks | |
| Mangos | 55 | 85 to 90 | 2 to 3 weeks | 30.3 |
| Nectarines | 31 to 32 | 90 | 2 to 4 weeks | 30.4 |
| Olives, fresh | 45 to 50 | 85 to 90 | 4 to 6 weeks | 29.4 |
| | 40 10 00 | 00 10 90 | 4 to 0 weeks | 40.7 |
| Oranges, California and Arizona | 38 to 48 | 85 to 90 | 3 to 8 weeks | 29.7 |
